## ABSTRACT

In this research, the authors succeeded in creating facial expressions made with the minimum necessary elements for recognizing a face. The elements are two eyes and a mouth made using precise circles, which are transformed to make facial expressions geometrically, through rotation and vertically scaling transformation. The facial expression patterns made by the geometric elements and transformations were composed employing three dimensions of visual information that had been suggested by many previous researches, *slantedness* of the mouth, *openness* of the face, and *slantedness* of the eyes. The authors found that this minimal facial expressions can be classified into 10 emotions: happy, angry, sad, disgust, fear, surprised, angry\*, fear\*, neutral (pleasant) indicating positive emotion, and neutral (unpleasant) indicating negative emotion. The authors also investigate and report *cultural differences* of impressions of facial expressions of above-mentioned simplified face.

## 1 INTRODUCTION

When human beings communicate with each other, their faces convey the most important and richest information, and their facial expressions are by far the most essential element for understanding the other's emotion. Various elements such as the eyes, mouth, and nose are contained in the face, and these are transformed to form

facial expressions. Geometric transformation is the method we use to make expressions. For many primates including human beings, the eyes are one of the most important factor used to recognize a face as a face.[1, 11, 17, 26] In addition, visual preference for facial figures (patterns in which three figures are arranged at the top of an upside-down triangle) and research on perceptions of upside-down faces are well known regarding facial recognition.[2, 12, 18, 25] These research results have suggested that primates recognize faces as sets of configural information comprised of facial elements, and in particular, the eyes and the mouth are the most important elements of all.

Meanwhile, there have been two theories regarding the recognition of facial expressions: the *category perception theory* and the *dimension theory*.[9, 19, 24] The category perception theory states that human beings judge the meaning of facial expressions through  $7 \pm 2$  universal categories common to all human beings. This theory is based on a basic theory of cognition and emotion stemming from evolutionary theory.[6, 25] Those who advocate this theory insist that facial expression is not a continuous variate but a discrete variate, and deny the presence of the psychological dimension described later in the cognitive process of expression.[24] In terms of emotional categories, the six basic emotions (happy, angry, sad, disgust, fear, and surprise) advocated by Ekman and many other researchers are the most typical. Basic emotions synchronize with physiological responses and signals to the body such as facial expressions,[6] and it is proposed that facial expressions can be classified under one of the six basic emotions without exception irrespective of culture.[3–5, 7, 8, 10]

The dimension theory proposes that affective category judgment is conducted following previous judgment that the facial expression is located as one point in two or three dimensional space, and that facial expression is a continuous variate.[9, 24] In addition, those who advocate this theory insist that the universal factor for human beings is not category but dimension.[13] Dimension theory begins with Schlosberg's theory of the dimension of emotion, for example the circular ring model[14] comprising two dimensions, namely pleasant vs. unpleasant and attention vs. rejection, and the circular cone model[15] comprising the previous two dimensions plus tension vs. sleep.[9, 16, 24] Since this research, many researchers have discussed such affective meaning dimensions and have repeatedly encountered three dimensions: the pleasantness dimension (pleasant vs. unpleasant), the attention vs. rejection dimension, and the activeness (awareness) dimension (aware vs. asleep).[9, 16, 19, 24] Especially in recent times, the circumplex model comprising a pleasantness dimension and an awareness dimension suggested by Russell has been validated in terms of its universality and robustness by many previous researches.[13, 16, 20]

Yamada conducted a study to clarify visual information (the physical variable) related to the cognition of facial expressions using a line-drawing figure in which eight points of the eyebrows, eyes and mouth are manipulated. From the results, two physical variables have been found: *slantedness*, meaning the curve and indication of face elements; and *openness* and curvedness, meaning the level of curve and openness of facial elements. In addition, they have suggested that there are strong relationships between slantedness and the pleasantness dimension, and between openness and activeness.[21–23] Based on this knowledge, they proposed that there are three processes used to cognize facial expressions: (1) acknowledgement of visual information (the physical variable) of the face, (2) evaluation of affective meaning based on the physical variable, and (3) judgment of the emotional category based on affective meaning.[24]

## 2 MINIMAL FACIAL EXPRESSIONS

The objective of this article is to validate the relationship between the physical variable and the affective variable discovered by previous researches using geometrical faces, and to apply the existing knowledge to robot facial design. Clarification of this relationship is one of the most important aspects for research on cognition of facial expression. The geometrical face used for this article is comprised of the minimum necessary elements for recognizing the face, and the elements are transformed geometrically to form the various facial expression patterns. The author introduces the physical variables, slantedness and openness, to the geometrical transformation. These facial patterns are classified by basic emotions, and evaluation of the relationship between the physical and affective variables is conducted by applying principal component analysis to the facial expression space centered on physical variables. Based on the results of the research, the author finally developed a model to create facial expressions.

By not using a realistic-looking human face, but rather a face made with limited elements and employing geometrical transformation, the relationship between the elements and factors used in making facial expression is shown more clearly. In addition, the result of this relationship expands in application to not only robot facial design, but also to medical fields such as curing cognitive impairment of facial expression. Thus, it is aimed to apply the results of this research to other fields.

### 2.1 The Design

The elements composing the face are limited to just three: the two eyes and the mouth, composed of precise circles and placed on the top of the upside-down triangle, the face figure (Fig. 1). Facial expression patterns are made by adding transformations to the three elements within the two parameters of *slantedness* and *openness*, comprising the physical variable for cognition of facial expressions. Slantedness of the eyes is a parameter that expresses the curve according to the opening of the eyes by their rotational deformation, while slantedness of the mouth expresses the rise or fall of the corners of the mouth. Openness is a parameter that expresses the change in the opening state of the eyes and mouth by the change in the vertically scaling transformation of the precise circle. Fig. 2 Left and Right show the changes to the eyes and

Figure 1: Left: Basic face before transformation; Right: Transformation of eyes by each parameter

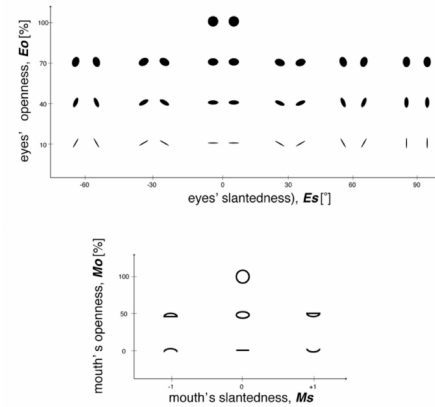

Figure 2: Left: Transformation of eyes by each parameter; Right: Transformation of mouth by each parameter

mouth according to the value of the parameters. The eyes make 19 patterns and mouth makes 7 patterns as shown in Fig. 2 Left and Right, making a total of 133 expression patterns. The facial expression is assumed to be completely facing the observer, and all faces are symmetrical.

Thus, each facial expression is defined by four values: two parameters of the eyes and two of the mouth, namely slantedness and openness respectively. So, the coordinates of one face can be shown as in the following mathematical expression:

$$\vec{f}_i = (E_{s_i} \ E_{o_i} \ M_{s_i} \ M_{o_i})^T \quad (1)$$

where  $i \in \{1, 2, \dots, n\}$ .

The above mathematical expression shows the coordinates of the  $i$ th facial expression, where  $E_s$  and  $E_o$  represent the eyes' slantedness and openness respectively, and  $M_s$  and  $M_o$  represent the mouth's slantedness and openness respectively. By principal component analysis we would be able to reduce dimensions of the space that  $\vec{f}_i$  spans and get  $\vec{f}'_i \approx \vec{f}_i$  where  $\dim \vec{f}' < \dim \vec{f}$ .

### 2.2 Classification of Facial Expression Patterns

The obtained expression patterns are classified by emotional category. For the emotional categories, the author uses the six basic emotions (happy, angry, sad, disgust, fear, and surprised) advocated by Ekman and many other researchers. In this article, the author additionally utilizes a neutral (pleasant) emotion, displaying no

emotion but showing a pleasant expression, and a neutral (unpleasant) emotion, showing no emotion but displaying an unpleasant expression, in order to research the facial expressions of neutral emotions. Clarification of the neutral face is important for robot faces, especially for humanoid robots without the function of forming facial expressions. In total, the eight emotional categories are defined.

Classification of facial expression patterns is conducted through an identification task. There are three rules for this task as follows: (1) the answerer must choose one emotion category for one face; (2) the answerer may adopt the same emotion category for more than one face; (3) the answerer does not need to select an emotion category if no category fits the face.

### 2.3 Distributing Facial Expression Patterns in Mathematical Space

As described in 2.1, each expression is defined by four-dimensional coordinates. Based on these coordinates, the author distributes the classified facial expression patterns in four-dimensional space. The facial patterns distributed in space are the faces selected by more than  $p/2$  answerers ( $p$  is the maximum number of answerers selecting the face as the emotion category).

After creating the facial expression space, analysis is applied to the space and the dimensions of the space are reduced to render it perceptible to the human eye. Through this analysis and visualization, the author can observe the difference in spatial distribution and parametric values of each facial pattern.

## 3 RESULT OF CLASSIFICATION AND SPATIAL DISTRIBUTION OF FACIAL EXPRESSIONS

From the results of the principal component analysis, the face distribution space is composed of three variables: openness of the mouth, slantedness of the eyes, and openness of the face. Moreover, this result almost completely concurs with expression distributions in the space composed of the emotional meaning dimension in previous research, and shows similarity to the results of expression cognition research using faces of actual human beings.

In addition, the research of the past is consolidated, and 10 basic facial expressions—happy, angry, angry\*, sad, disgust, fear, fear\*, surprised, neutral (pleasant), and neutral (unpleasant)—are advocated.

### 3.1 Three-Dimensional Space for Distribution of Face

The identification task was undertaken by 140 men and women ranging in age from their teens to their 60s. (average age in their 20s). The results of the principal component analysis of four-dimensional space are shown in Table 1. Four-dimensional space can be reduced to three-dimensional space from the result of the cumulative proportion from principal component-1 to principal component-2, shown to be 0.807. In addition, the value of each principal component is shown in Table 2. Principal component-1 was judged to mean the slantedness of the mouth; principal component-2 shows the slantedness of mouth; and principal component-3 shows the openness of the face, meaning openness of both eyes and mouth,

**Table 1: Result of principal component analysis**

Principal component (PC)	PC1	PC2	PC3	PC4
Standard deviation	1.119	1.034	0.951	0.873
Cumulative proportion	0.313	0.581	0.807	1.00

according to this value. This result corresponded to the three types of visual information (the visual variable) that had been obtained by previous researches.[3, 4, 6, 13]

To assess the relationship between the emotional meaning dimension obtained by this research and the visual information dimension obtained by previous researches, the author compared two planes, a projection plane of three-dimensional space obtained by this research comprising slantedness of mouth and openness of face, and a plane comprising the pleasantness dimension and the activeness dimension,[24] which have strong relationships with the slantedness of the mouth and the openness of the face.[5, 7] The former plane is shown in Fig. 3 Left, and the latter in Fig. 3 Right. Each facial expression is assigned a weight according to the number of selections. An important point in Fig. 3 Center and Fig. 3 Right is that the average coordinates of each emotion category took these weights into consideration.

Comparing Fig. 3 Left and Fig. 3 Right, the distribution of happy, surprised, and fear can be seen to almost correspond, and in addition, angry, sad, and disgust were also seen to correspond in terms of closeness of distribution. Moreover, fear could be seen to separate into two clusters in terms of distribution, which could be read in Fig. 3 Left. As mentioned above, the author determined that the distribution of the facial expressions in three-dimensional space obtained through this article was valid.

In addition, angry, sad and disgust were separately observed by constructing and observing a projection plane of three-dimensional space comprising slantedness of the eyes and openness of the face (Fig. 3 Right). From this result, by considering the third dimension, the slantedness of the eyes, the distribution of each facial expression was easy to separate and read. Thus the author discovered that the visual information dimension (physical variable) comprises three variables for cognizance of facial expressions.

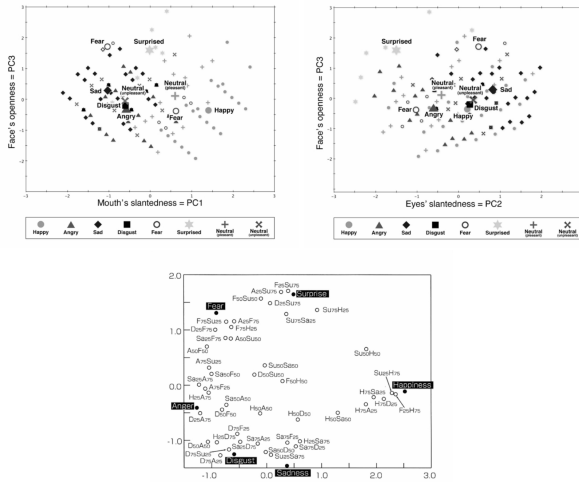

### 3.2 Eight Facial Expressions and Two Neutral Facial Expressions

In addition to the observation of face distributions in space, the author found 10 basic facial expressions, eight basic facial expressions: happy, angry, angry\*, sad, disgust, fear, fear\*, and surprised; and two neutral facial expressions: neutral (pleasant) and neutral (unpleasant), according to the parametric values and actual facial patterns. The difference between angry and angry\* is especially apparent in terms of the openness of the eyes and mouth, so angry can be separated in terms of the facial expression showing the anger emotion. Moreover, it can be seen that fear and fear\* can be separated because the slantedness of the eyes and the mouth indicate an opposite value.

Furthermore these facial expressions are distributed in three-dimensional space based on continuous geometrical transformation

**Table 2: Meaning of each principal component**

Principal component (PC)		PC1	PC2	PC3
Eyes	Slantedness	0.280	-0.773	-0.298
	Openness	0.557	0.125	0.749
Mounth	Slantedness	0.674	-0.137	-0.160
	Openness	-0.396	-0.609	0.570
Meaning of PC		Mouth's slantedness	Eye's slantedness	Face's openess

**Figure 3: Left: Projection plane of three-dimensional space for facial expression composed of slantedness of the mouth and openness of the face; Center: Projection plane of three-dimensional space for facial expressions composed of the slantedness of the eyes and the openness of the face; Right: Circumplex mode constructed by Takehara & Suzuki (2001)**

of the eyes and mouth, and it is understood that each facial expression generates a network comprising a visual and a physical variable (geometrical transformation).

#### 4 DISCUSSION AND CONCLUSION

Through the facial expression pattern presented in this article, the visual variable dimension was obtained, namely, the slantedness of the eyes, the slantedness of the mouth, and the openness of eyes and mouth. Moreover, by observation and comparing with three-dimensional space and the results of previous research, it was found that there is a strong relationship between the slantedness of the mouth and the pleasantness dimension, and the openness of the eyes and mouth and activeness, as indicated in previous research.

In addition, based on observation of the distribution in three-dimensional space, the slantedness of the eyes is an effective means of discerning the distribution areas of the facial expressions, especially angry, sad and disgust. Thus the third effective variable's dimension serves to aid cognition of facial expression, and bears a strong relationship with the judgment of angry, sad and disgust.

In this article, the neutral (pleasant) and neutral (unpleasant) expressions were added to the classification of facial expressions. These expressions were found to exist even though they do not show a specific emotion, and these neutral facial expressions can be generated through transformation of facial elements. Moreover, according to the facial pattern, the neutral face can be divided into two facial expressions, showing pleasant and unpleasant emotions respectively. From the results of observing the spatial and geometrical differences between faces, the author defined the neutral (pleasant) facial expression as between happy and surprised, and the neutral (unpleasant) expression as between happy and sad.

In this research, the authors succeeded in creating facial expressions made with the minimum necessary elements for recognizing a face, and enabling human recognition of the expressions created. The elements used for the minimal face were two eyes and a mouth made by precise circles and transformed to make facial expressions geometrically, through rotation and vertically scaling transformation. The facial expression patterns made by the geometric elements and transformations comprised three dimensions of visual information (visual variables) that had been suggested by many previous researches: slantedness of the mouth, openness of face, and slantedness of the eyes. Thus the results of this research indicate that human beings can classify expression patterns of minimal faces to particular emotional categories just as they would with an actual human face. In addition, the relationships between visual affection dimension and the affective meaning dimension also corresponded to the results of the previous researches. These relationships were strong between the slantedness of the mouth and pleasantness; and between the openness of the face and activeness; and the existence of a third affective variable strongly related to the slantedness of the eyes was also suggested.
